```

Q1: How many observations are in this dataset?

```
dim(wisc.data)
```

```
## [1] 569  30
```

It looks like there is 569 different observations.

Q2: How many of the observations have a malignant diagnosis?

```r
table(diagnosis)
```

```
## diagnosis
##   B   M 
## 357 212
```

There is 212 malignant observations

Q3: How many variables/features in the data are suffixed with _mean?

```r
length(grep("_mean", colnames(wisc.data)))
```

```
## [1] 10
```

10 columns have the term “_mean” in them

Next: PCA

Check column means and standard deviations

```r
colMeans(wisc.data)
```

```

```

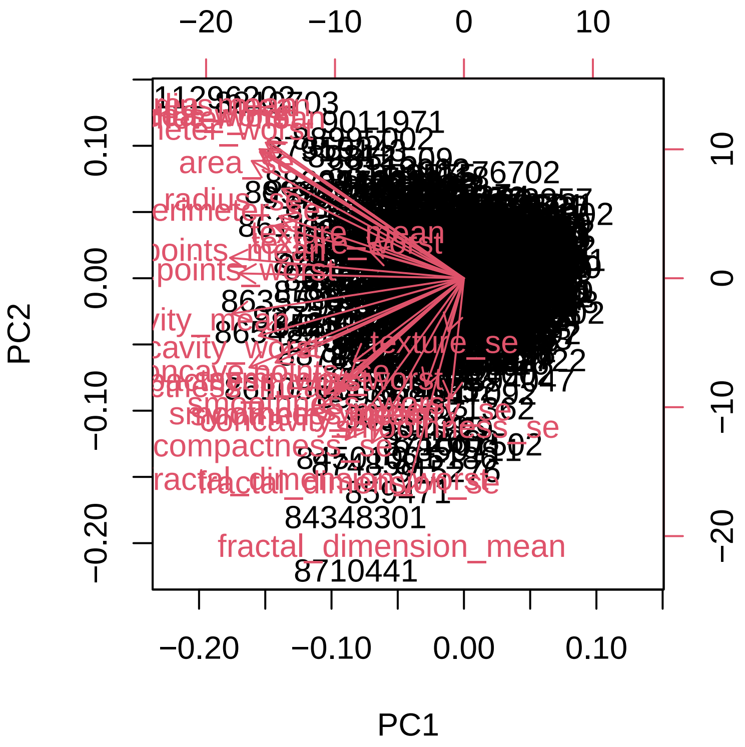
Q4: From your results, what proportion of the original variance is captured by the first principal components (PC1)? 44.27%

Q5: How many principal components (PCs) are required to describe at least 70% of the original variance in the data? 3

Q6: How many principal components (PCs) are required to describe at least 90% of the original variance in the data? 7

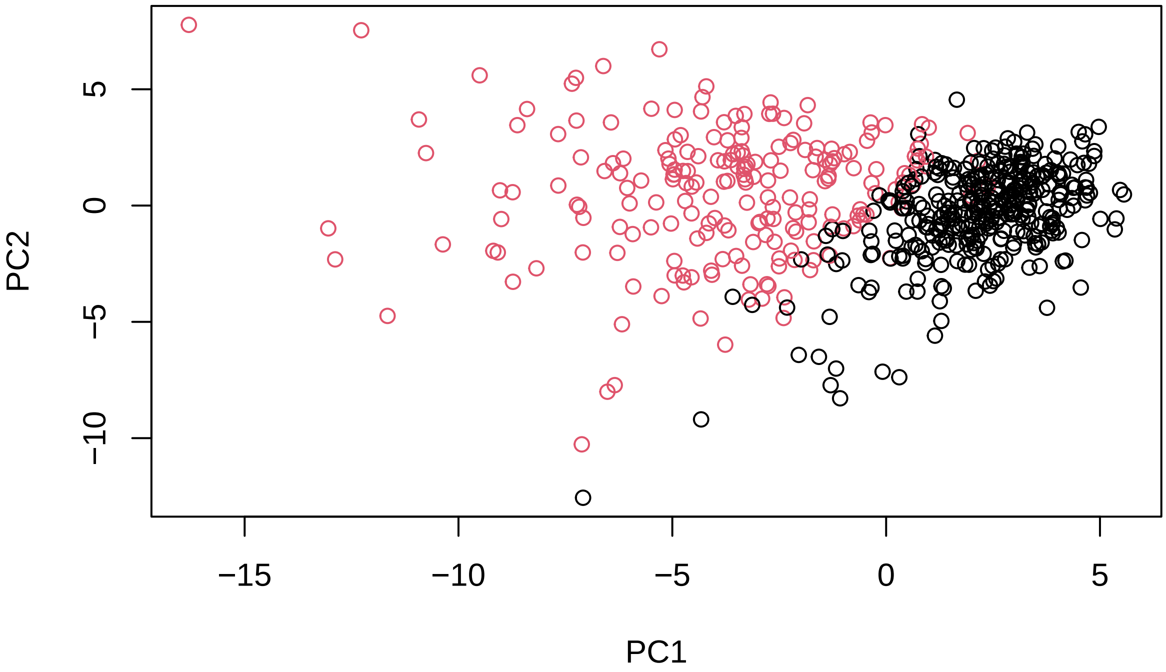
```
biplot(wisc.pr)
```



Q7: What stands out to you about this plot? Is it easy or difficult to understand? Why?

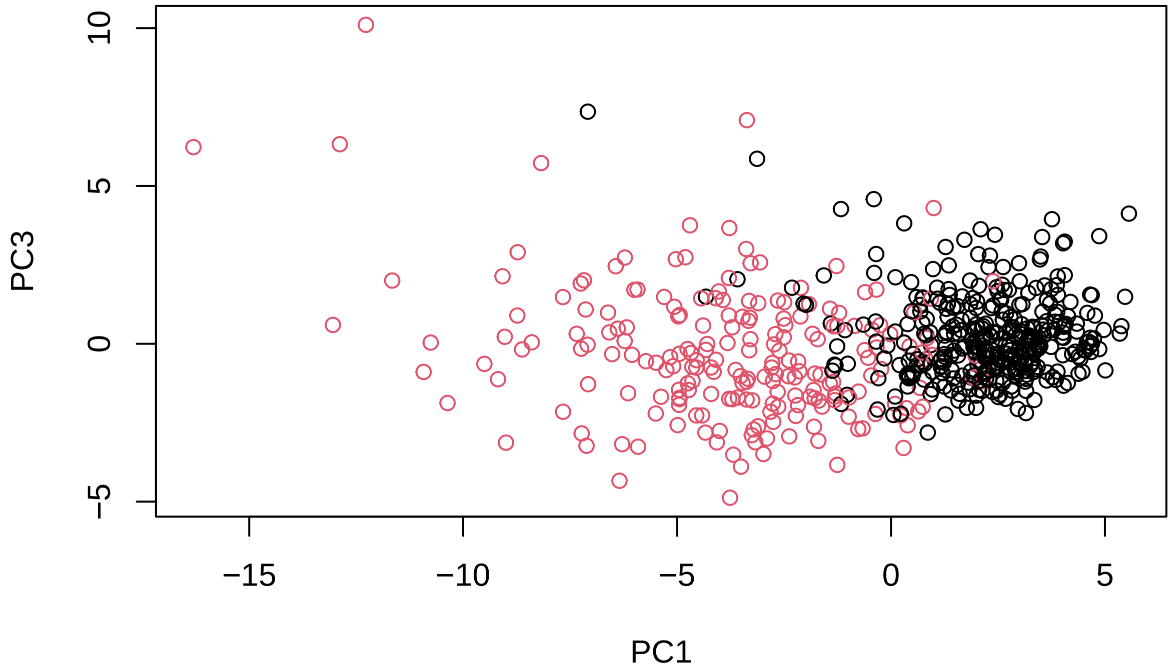
Can’t understand anything on the plot, impossible to read

```
plot( wisc.pr$x , col = diagnosis ,
     xlab = "PC1", ylab = "PC2")
```



Q8: Generate a similar plot for principal components 1 and 3. What do you notice about these plots?

```
plot( wisc.pr$x[, c(1,3)] , col = diagnosis ,
   xlab = "PC1", ylab = "PC3")
```

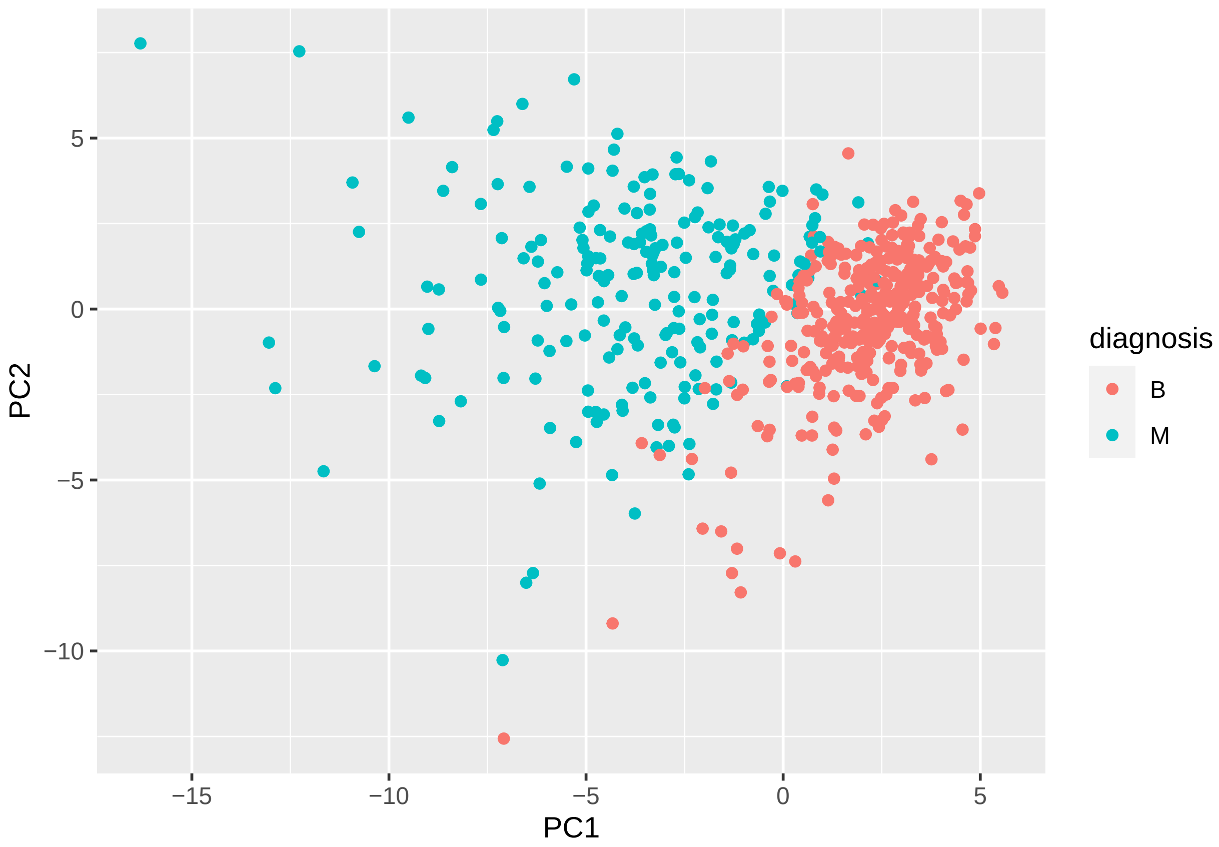


There seems to be two different cluster of cells, red dots(or malignant) and black dots (or benign)

Creating ggplot for our data

```
df <- as.data.frame(wisc.pr$x)
df$diagnosis <- diagnosis
```

```
library(ggplot2)
ggplot(df) + aes(PC1, PC2, col=diagnosis) +
  geom_point()
```

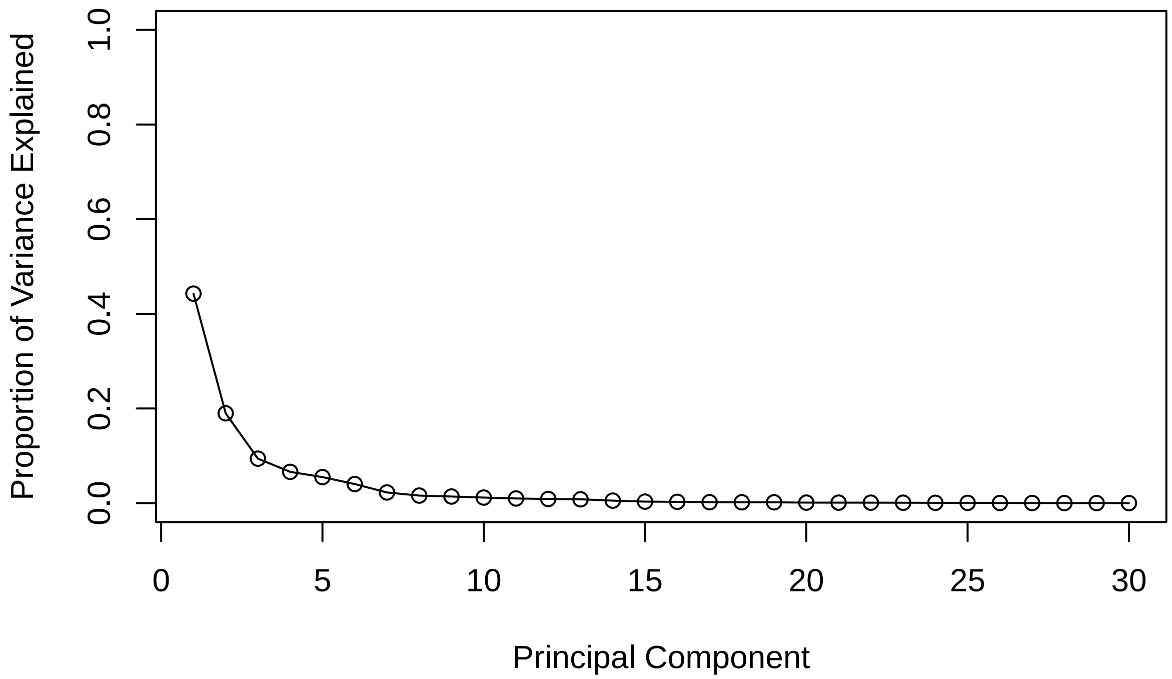


Calculating the variance now

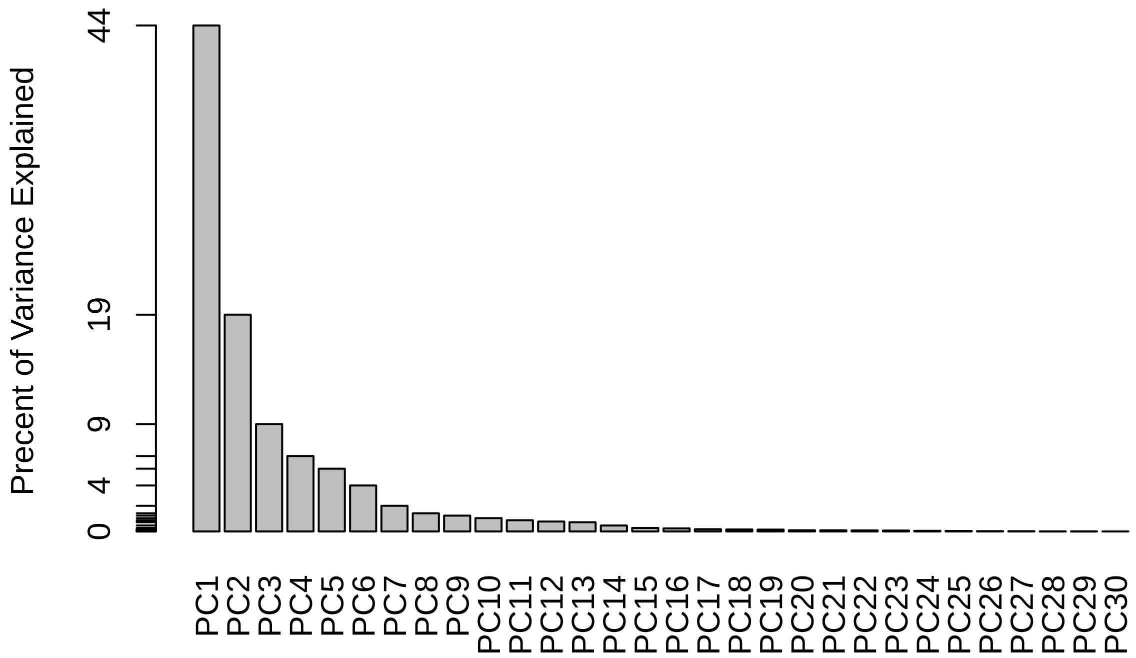
```
pr.var <- wisc.pr$sdev^2
head(pr.var)
```

```
## [1] 13.281608  5.691355  2.817949  1.980640  1.648731  1.207357
```

```
pve <- pr.var/(sum(pr.var))
plot(pve, xlab = "Principal Component",
     ylab = "Proportion of Variance Explained",
     ylim = c(0, 1), type = "o")
```



```
barplot(pve, ylab = "Precent of Variance Explained",
     names.arg=paste0("PC",1:length(pve)), las=2, axes = FALSE)
axis(2, at=pve, labels=round(pve,2)*100 )
```



Q9: For the first principal component, what is the component of the loading vector (i.e. wisc.pr$rotation[,1]) for the feature concave.points_mean?

```
wisc.pr$rotation["concave.points_mean",1]
```

```
## [1] -0.2608538
```

Q10: What is the minimum number of principal components required to explain 80% of the variance of the data?

```
summary(wisc.pr)
```

```
## Importance of components:

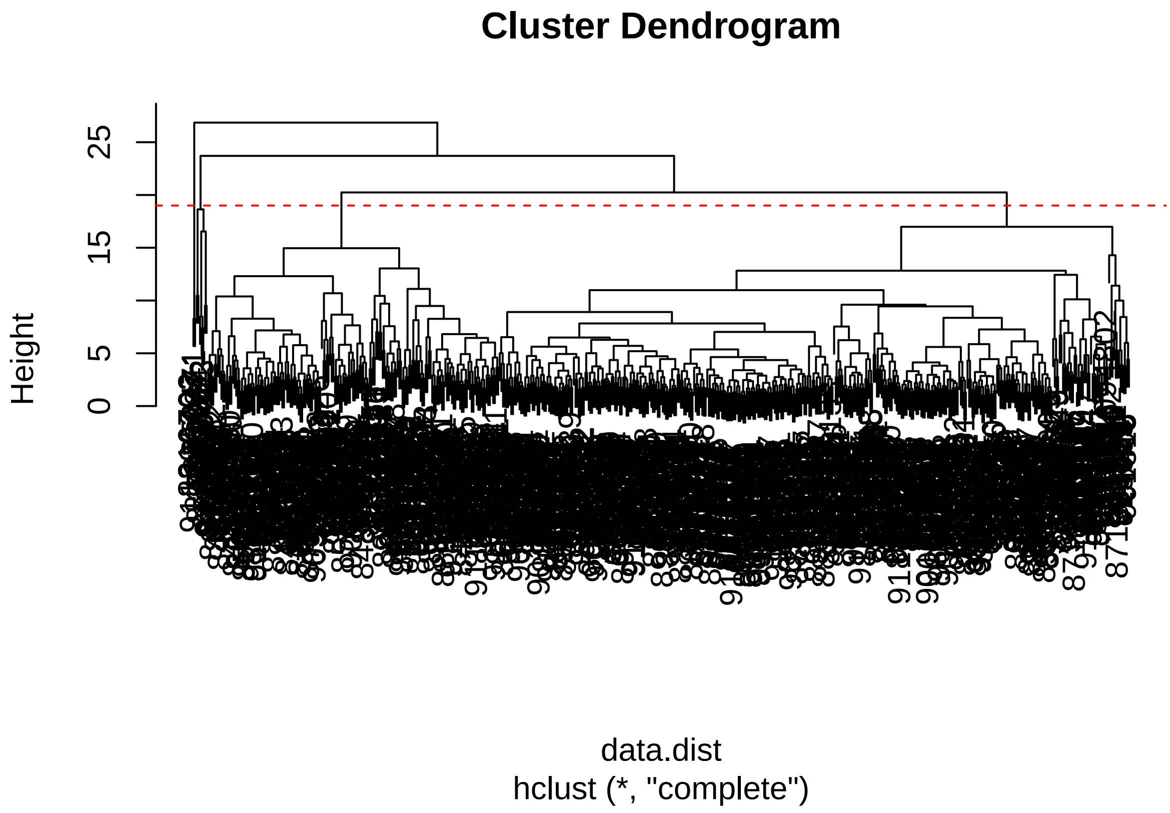
```

We need The first 5 PCs to get to at least 80%

Q11: Using the plot() and abline() functions, what is the height at which the clustering model has 4 clusters? *Hierarchical clustering*

```
data.scaled <- scale(wisc.data)
data.dist <- dist(data.scaled)
wisc.hclust <- hclust(data.dist)
plot(wisc.hclust) +
abline(h=19, col="red", lty=2)
```



```
## integer(0)
```

Height 19 gives us 4 clusters.

```
wisc.hclust.clusters <- cutree(wisc.hclust, h=19)
table(wisc.hclust.clusters, diagnosis)
```

```
##                     diagnosis
## wisc.hclust.clusters   B   M
##                    1  12 165
##                    2   2   5
##                    3 343  40
##                    4   0   2
```

Q12. Can you find a better cluster vs diagnoses match by cutting into a different number of clusters between 2 and 10?

```
wisc.hclust.clusters <- cutree(wisc.hclust, h=10)
table(wisc.hclust.clusters, diagnosis)
```

```
##                     diagnosis
## wisc.hclust.clusters   B   M
##                   1    0  24
##                   2    0  53
##                   3    0   3
##                   4    0  11
##                   5   12  46
##                   6  100  33
##                   7    0  14
##                   8  197   6
##                   9    0   5
##                   10  19   0
##                   11  11   0
##                   12   1   0
##                   13  10   0
##                   14   0   2
##                   15   0   6
##                   16   1   0
##                   17   0   6
##                   18   4   0
##                   19   0   2
##                   20   0   1
##                   21   2   0
```

```
wisc.hclust.clusters <- cutree(wisc.hclust, h=20)
table(wisc.hclust.clusters, diagnosis)
```

```
##                     diagnosis
## wisc.hclust.clusters   B   M
##                    1  12 165
##                    2   2   5
##                    3 343  40
##                    4   0   2
```

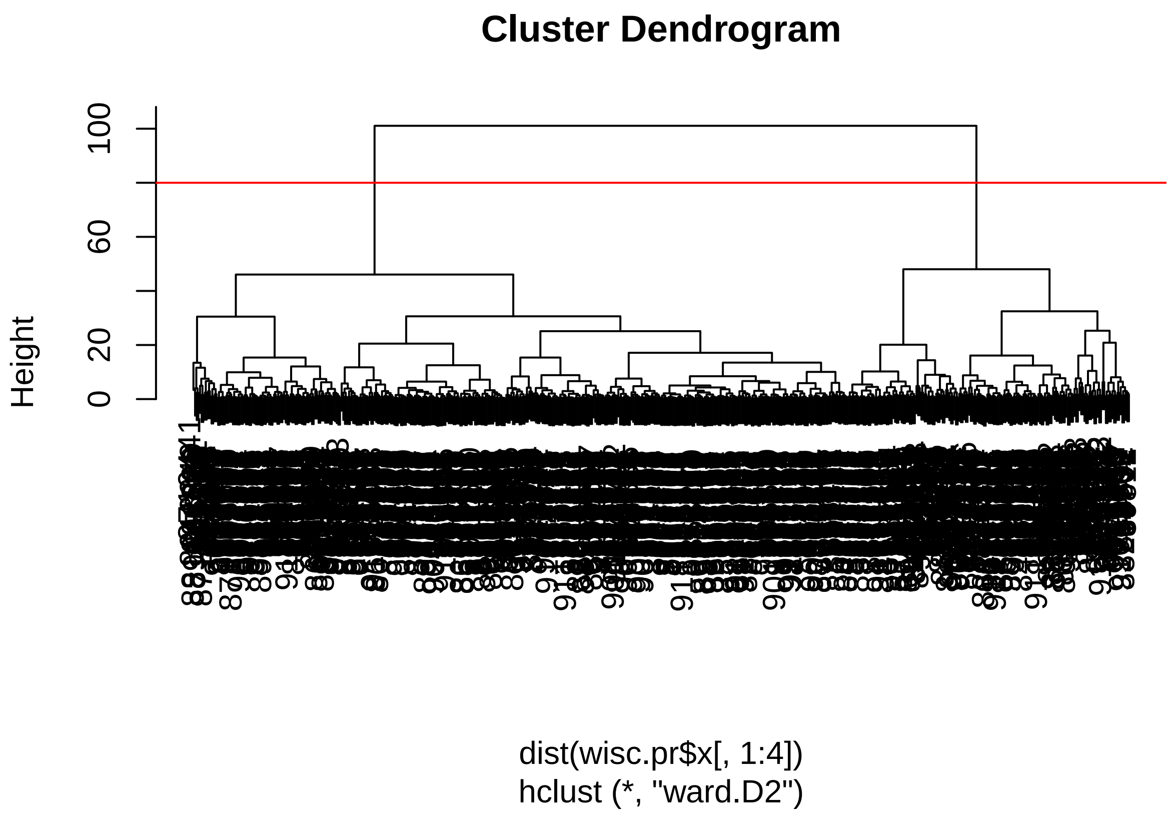
```
wisc.hclust.clusters <- cutree(wisc.hclust, h=24)
table(wisc.hclust.clusters, diagnosis)
```

```
##                     diagnosis
## wisc.hclust.clusters   B   M
##                    1 357 210
##                    2   0   2
```

It seems that height 19-20 gives us the best clusters.

Q13. Which method gives your favorite results for the same data.dist dataset? Explain your reasoning.

```
wisc.pr.hclust <- hclust(dist(wisc.pr$x[,1:4]), method="ward.D2")
plot(wisc.pr.hclust)
abline(h=80, col="red")
```



Q15: How well does the newly created model with four clusters separate out the two diagnoses?

```
grps <- cutree(wisc.pr.hclust, k=2)
table(grps)
```

```
## grps
##   1   2
## 171 398
```

Comparing it to the expert M and B vector

```
table(diagnosis)
```

```
## diagnosis
##   B   M
## 357 212
```

We can do a cross-table by giving the table() function two inputs. (Called confusion table)

```
table(grps, diagnosis)
```

```
##     diagnosis
## grps   B   M
##    1   6 165
##    2 351  47
```

Accuracy, essentially how many did we get correct?

```
(165+351)/nrow(wisc.data)
```

```
## [1] 0.9068541
```

Q17: Which of your analysis procedures resulted in a clustering model with the best specificity? How about sensitivity?

Sensitivity

```
165/(165+47)
```

```
## [1] 0.7783019
```

Specificity

```
351/(351+47)
```

```
## [1] 0.8819095
```

```
url <- "new_samples.csv"
new <- read.csv(url)
npc <- predict(wisc.pr, newdata=new)
npc
```

```
##            PC1       PC2        PC3        PC4       PC5        PC6        PC7
